Hypothesis: $h_{\theta}(x) = \theta_0 + \theta_1 x$

θ_i : Parameters

How to choose θ_i 's ?

$$h_{\theta}(x) = \theta_0 + \theta_1 x$$

$$\theta_0 = 1.5$$
$$\theta_1 = 0$$

$$\theta_0 = 0$$
$$\theta_1 = 0.5$$

$$\theta_0 = 1$$
$$\theta_1 = 0.5$$

Idea: Choose θ_0, θ_1 so
 that \hat{y}
 is close to y (for)
 our training

Machine Learning

Linear regression with one variable Gradient descent

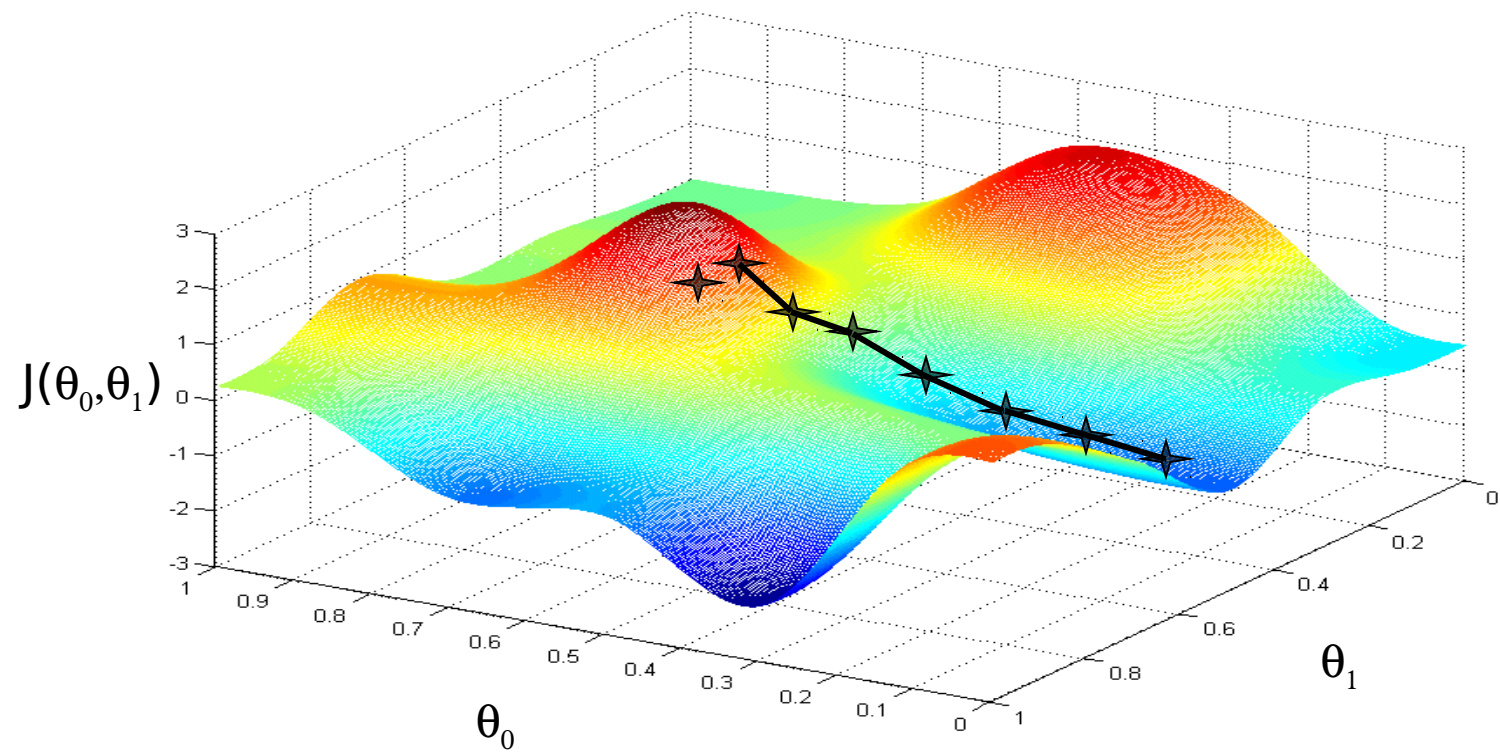

Have some function $J(\theta_0, \theta_1)$

Want $\min_{\theta_0, \theta_1} J(\theta_0, \theta_1)$

Outline:

- Start with some θ_0, θ_1
- Keep changing θ_0, θ_1 to reduce $J(\theta_0, \theta_1)$
until we hopefully end
up at a minimum

Gradient descent algorithm

repeat until convergence {
 $\theta_j := \theta_j - \alpha \frac{\partial}{\partial \theta_j} J(\theta_0, \theta_1)$ (for $j = 0$ and $j = 1$)
}

Correct: Simultaneous update Incorrect:

$\text{temp0} := \theta_0 - \alpha \frac{\partial}{\partial \theta_0} J(\theta_0, \theta_1)$
 $\text{temp1} := \theta_1 - \alpha \frac{\partial}{\partial \theta_1} J(\theta_0, \theta_1)$
 $\theta_0 := \text{temp0}$
 $\theta_1 := \text{temp1}$

$\text{temp0} := \theta_0 - \alpha \frac{\partial}{\partial \theta_0} J(\theta_0, \theta_1)$
 $\theta_0 := \text{temp0}$
 $\text{temp1} := \theta_1 - \alpha \frac{\partial}{\partial \theta_1} J(\theta_0, \theta_1)$
 $\theta_1 := \text{temp1}$

Gradient descent algorithm

repeat until convergence {
 $\theta_j := \theta_j - \alpha \frac{\partial}{\partial \theta_j} J(\theta_0, \theta_1)$ (simultaneously update
 $j = 0$ and $j = 1$)
}

$$\theta_1 := \theta_1 - \alpha \frac{\partial}{\partial \theta_1} J(\theta_1)$$

If α is too small, gradient descent can be slow.

If α is too large, gradient descent can overshoot the minimum. It may fail to converge, or even diverge.

Gradient descent can converge to a local minimum, even with the learning rate α fixed.

$$\theta_1 := \theta_1 - \alpha \frac{d}{d\theta_1} J(\theta_1)$$

As we approach a local minimum, gradient descent will automatically take smaller steps. So, no need to decrease α over time.
